 - * Self-Assembly, Self-Recognition, and Self-Organization
- * Thermodynamics, Information, and Entropy

Authors (1)

- * Jean-Marie Lehn
 - * Winner of The Nobel Prize in Chemistry 1987

Authors (2)

- * Tanya Sienko
 - * Coauthor of “Molecular Computing”

Molecular Computing Basics (1)

- * physical base underlying every computing system
 - * semi-conductor material
 - * more complicated organic chemical
- * Reverse the demarcation of computing into “hardware” and “software”
 - * cannot make a distinction
- * instead of “programmability”,
 - * “evolution”,
 - * “adaptability,”
 - * and “informed materials”

Molecular Computing Basics (2)

- * “information” lie in
 - * chemical
 - * supramolecular attributes and behavior
- * gains ability of implementing
 - * “recognition,”
 - * self-organization,
 - * and other “high-level” behaviors
- * molecular recognition
 - * supramolecular interaction algorithms

Covalent Chemistry (1)

- * assemble molecules from atoms or smaller molecules

- * Structure and functionality depend on the nature of the atoms and on their geometrical arrangement

Covalent Chemistry (2)

- Ionic bond : $\approx 400 \text{ kJ}\cdot\text{mol}^{-1}$

Na^+ Cl^-

276 pm

NaCl crystal

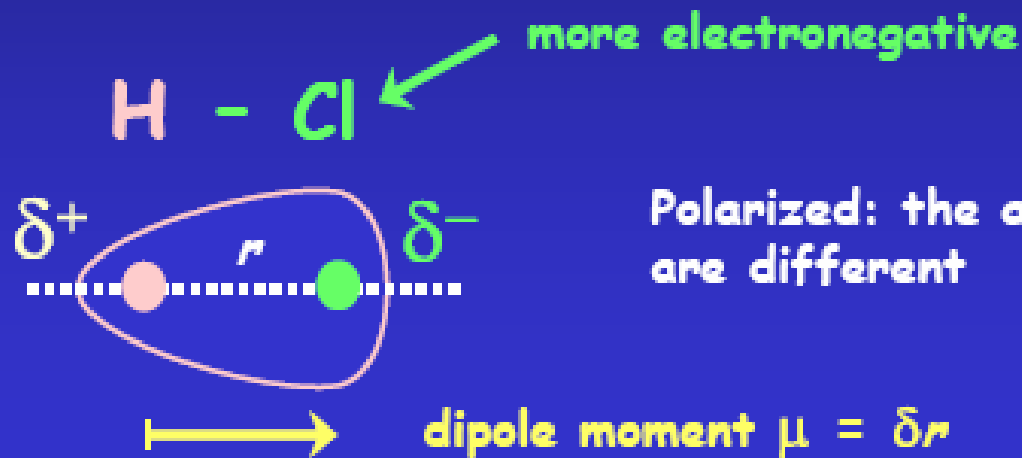

Covalent Chemistry (3)

• Covalent bond : $\approx 350-450 \text{ kJ}\cdot\text{mol}^{-1}$

Apolar: the atoms are identical

Polarized: the atoms are different

Covalent Chemistry (4)

Carbon dioxide

fructose

Crown ether

cholesterol

(R)-limonene

(S)-limonene

Some covalent molecules

Molecular Recognition – Definition (1)

- * Is the binding and specific selection of substrates by a given receptor molecule
 - * binding forms a complex, or supramolecule
- * Pattern-recognition process
- * Major difference – types of bond
 - * molecular chemistry - covalent bond
 - * supramolecular chemistry - noncovalent types of binding
 - * electrostatic interactions
 - * hydrogen bonding
 - * van der Waals forces
 - * etc

Molecular Recognition – Definition (2)

- * has a critical role to play in
 - * catalytic activity
 - * membrane transport
- * self-assembly and self-organization
- * most, if not all, biological processes involve a molecular recognition event at some stage

Molecular Recognition Basic

The lock and key principle: a molecular recognition principle

Pre-organised
Receptor
(host)

potential
guests

Host-guest complex

$$\Delta G_r < \Delta G_r, \Delta G_r$$

Molecular Recognition Basic

⚡ Lock and key principle (Emil Fischer, 1894)
(and induced fit principle)

⚡ Non-covalent interactions:

$\text{kJ} \cdot \text{mol}^{-1}$

• Electrostatic interactions:

ion-ion

ion-dipole

}

200-400

hydrogen bonds

dipole-dipole

}

20-60

dispersion, induction forces
(van der Waals interactions)

5-20

Molecular Recognition Basic

- π - π stacking interactions
- hydrophobic effects or solvent effects
- steric effects

+ Self-assembly processes

Molecular Recognition Basic

Molecular Recognition Basic

- * Factors
 - * Steric (shape and size) complementarity
 - * Interactional complementarity
 - * Large areas of contact between receptor and substrate
 - * Multiple interaction sites
 - * Strong overall binding
 - * Inclusion and Dynamics
 - * Medium effects on molecular recognition

Contents

- * Molecular Computing Basics
- * Molecular Recognition
 - * Covalent Chemistry
 - * Definition
 - * Basics
 - * **Examples**
 - * Exoreceptors
 - * Sphers, Lines, and Tetrahedra
 - * Tetrahedral Recognition
 - * Other Types Molecules That Can Be Bound
 - * Anion Recognition
 - * Linear Recognition
 - * Multiple Recognition
 - * Chemical Systems
 - * Self-Assembly, Self-Recognition, and Self-Organization
- * Thermodynamics, Information, and Entropy

Examples (1)

- * Exoreceptors
 - * analogous to enzymes
- * the active sites are contained inside the cavity of a large protein molecule,
- * then binds a smaller substrate fitting into the cleft
- * most cavities range from approximately 2 to 15 angstroms

Examples (2)

cubic binding of K^+ into valinomycin

macrobicyclic ligands –
Spherical recognition

Examples (3)

ammonium cryptate - Tetrahedral Recognition

Ammonia in macrobicyclic receptor molecule

Binding of adenine in a cleft

Examples (4)

* Linear Recognition

Multiple Recognition

Cascade-type dinuclear copper (II) cryptate formed with a macrocyclic polyamine as the ligand. The copper ions bind first, followed by the imidazole groups.

Contents

 - * Basics
 - * Examples
 - * Multiple Recognition
 - * **Chemical Systems**
 - * Supramolecular Reactivity and Catalysis
 - * Carrier-Mediated Transport
 - * Photonic Molecular Devices
 - * Self-Assembly, Self-Recognition, and Self-Organization
 - * Micelles and LB Films
- * Thermodynamics, Information, and Entropy

Supramolecular Reactivity and Catalysis

(1)

Hypothetical structure of the ATP complex in the catalysis of ATP hydrolysis

Supramolecular Reactivity and Catalysis

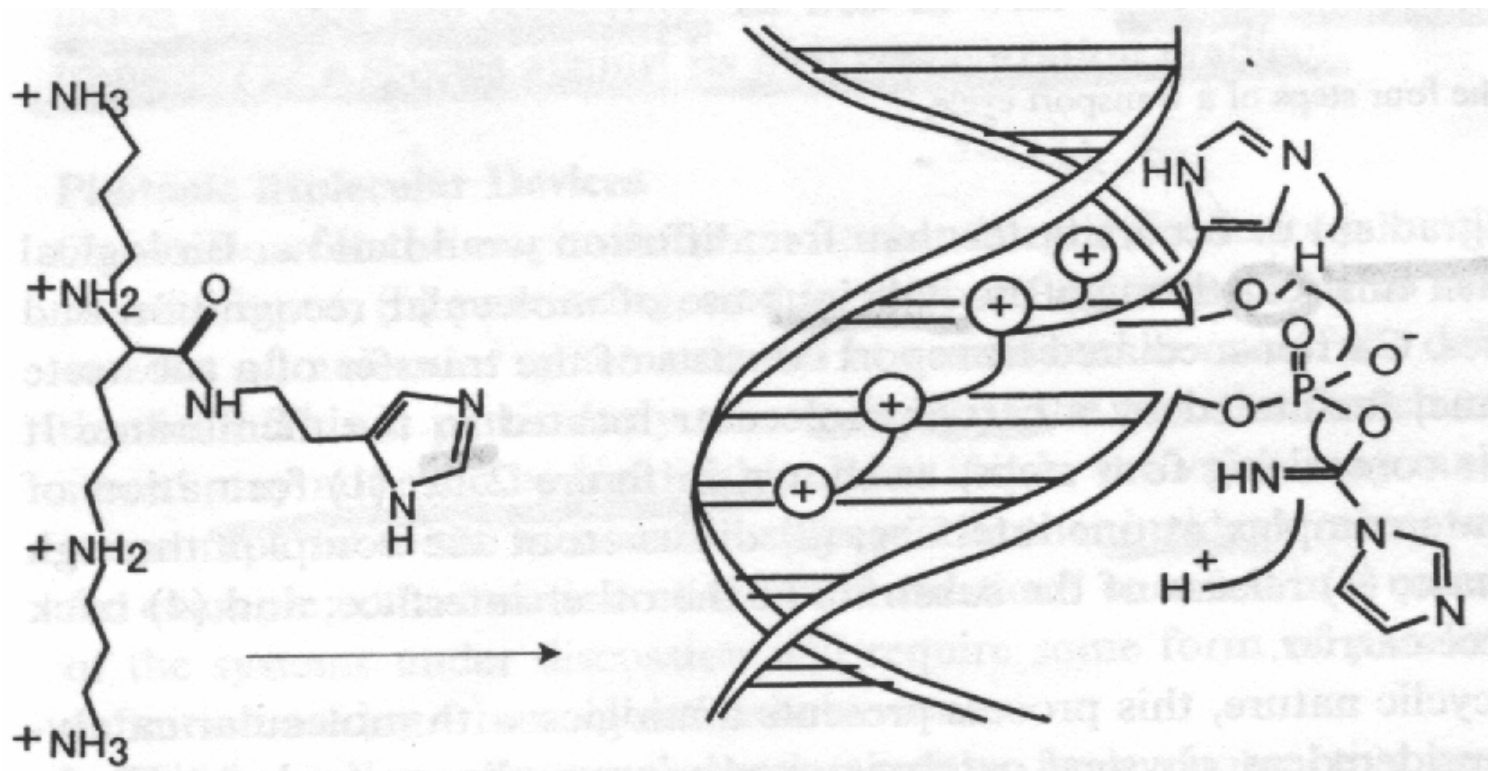

(2)

Cocatalysis cycle, with final products either being the transfer of a subunit or the ligation of two subunits.

Supramolecular Reactivity and Catalysis

(3)

Enhancement of ligation of DNA as effected by an imidazole-functionalized spermine binding in the minor groove of the double helix

Carrier-Mediated Transport

Photonic Molecular Devices

Eu(III) cryptate showing the three steps (absorption, energy taransfer, and emission) in light conversion

Self-Assembly, Self-Recognition, and Self-Organization (1)

1-step synthesis
ethylene glycol
170 °C

Chloride receptor

Self-Assembly, Self-Recognition, and Self-Organization (2)

Self-Assembly, Self-Recognition, and Self-Organization (3)

Self-Assembly, Self-Recognition, and Self-Organization (4)

Self-Assembly, Self-Recognition, and Self-Organization (5)

Supramolecular polymer

Lehn et al.

Barbituric acid deriv.

Deriv. Melamine

Self-Assembly, Self-Recognition, and Self-Organization (6)

Self-replicating system

1st step: covalent synthesis

Self-Assembly, Self-Recognition, and Self-Organization (7)

Self-replicating system

The product complexes the reagents, which induces the chemical reaction

Contents

- * Molecular Computing Basics
- * Molecular Recognition
 - * Covalent Chemistry
 - * Definition
 - * Basics
 - * Examples
 - * Multiple Recognition
 - * Chemical Systems
 - * Self-Assembly, Self-Recognition, and Self-Organization
- * **Thermodynamics, Information, and Entropy**

Thermodynamics, Information, and Entropy (1)

- * Factor must be considered
 - * the interplay of limitations on information
 - * entropy
 - * whereas not about most present computer systems
- * How to read information in and out
 - * self-organizing behavior may work
 - * it may be impossible to easily access the information without
 - * erasing it
 - * perturbing it
 - * regeneration of the data
 - * may negate putative advantages

Thermodynamics, Information, and Entropy (2)

- * Chemical systems may store information either
 - * in an analog fashion; size, shape, nature, and disposition
 - * or in a digital fashion; states, connections
- * Recognition is a relative notion
 - * results from the structural information stored in the partners
 - * which rests on the difference in free energy of interaction between states
 - * depends on, consequently, temperature

Thermodynamics, Information, and Entropy (3)

- * these are all natural process
 - * entropy always increases
- * information transfer and self-replication
 - * a molecule catalyzes its own formation by acting as template
 - * constituents react to generate a copy of it
 - * may be termed informational

Thermodynamics, Information, and Entropy (4)

- * Another good features
 - * self-correction
 - * adaptation
- * pure compounds → instructed mixtures
- * unicity → multiplicity + information
- * Next step! “learning” systems
 - * not only instructed but can be trained
- * Third basic feature of chemical systems: information
 - * in addition to matter and energy
