# Molecular Computing for NBIC

# DNA Computation of Hamiltonian Paths

## Hamiltonian Path Problem

Consider a map of cities connected by certain nonstop flights (top right). For instance, in the example shown here, it is possible to travel directly from Boston to Detroit but not vice versa. The goal is to determine whether a path exists that will commence at the start city (Atlanta), finish at the end city (Detroit) and pass through each of the remaining cities exactly once. In DNA computation, each city is assigned a DNA sequence (ACTTGCAG for Atlanta) that can be thought of as a first name (ACTT) followed by a last name (GCAG). DNA flight numbers can then be defined by concatenating the last name of the city of origin with the first name of the city of destination (bottom right).

The complementary DNA city names are the Watson-Crick complements of the DNA city names in which every C is replaced by a G, every G by a C, every A by a T, and every T by an A. (To simplify the discussion here, details of the 3' versus 5' ends of the DNA molecules have been omitted.) For this particular problem,

only one Hamiltonian path exists, and it passes through Atlanta, Boston, Chicago and Detroit in that order. In the computation, this path is represented by GCAGTCG-GACTGGGCTATGTCCGA, a DNA sequence of length 24. Shown at the left is the map with seven cities and 14 nonstop flights used in the actual experiment. —L.M.A.

CITY	DNA NAME	COMPLEMENT
ATLANTA	ACTTGCAG	TGAACGTC
BOSTON	TCGGACTG	AGCCTGAC
CHICAGO	GGCTATGT	CCGATACA
DETROIT	CCGAGCAA	GGCTCGTT
FLIGHT	DNA FLIGHT NUMBER	
ATLANTA - BOSTON	GCAGTCGG	
ATLANTA - DETROIT	GCAGCCGA	
BOSTON - CHICAGO	ACTGGGCT	
BOSTON - DETROIT	ACTGCCGA	
BOSTON - ATLANTA	ACTGACTT	
CHICAGO - DETROIT	ATGTCCGA

**B**

$x_1=F, x_2=T, x_3=F, x_4=F, x_5=F, x_6=F, x_7=T, x_8=T, x_9=F, x_{10}=T,$   
 $x_{11}=T, x_{12}=T, x_{13}=F, x_{14}=F, x_{15}=T, x_{16}=T, x_{17}=T, x_{18}=F, x_{19}=F,$   
 $x_{20}=F$

**Fig. 1.** The computational problem. (A) 20-variable 3-CNF Boolean formula  $\Phi$ . The symbol “~” indicates “not.” (B) The unique truth assignment satisfying  $\Phi$ .

**Fig. 4.** The computer. An electrophoresis box 30 cm long, 15 cm wide, and 8 cm high was constructed from 0.5-cm-thick plexiglass. The box was partitioned into a hot chamber and a cold chamber of equal volumes, by a plexiglass divider. Each chamber was attached via plastic tubing to a circulating water bath. Water from the bath was transported across the chamber through copper tubing, acting as a cooling/heating coil. A platinum wire electrode was inserted into each chamber. For each of the 24 clauses of  $\Phi$ , a 100- $\mu$ l clause solution was prepared containing 15  $\mu$ M of each of three Acrydite-modified probes, one for each literal in the clause (if  $x_k$  appeared in the clause, the probe with sequence  $\bar{X}_k^T$  was added, if  $\sim x_k$  appeared, the probe with sequence for  $X_k^F$  was added).

For example, for the first clause, ( $\sim x_3$  or  $\sim x_{16}$  or  $x_{18}$ ), probes with sequences  $\bar{X}_3^T, \bar{X}_{16}^T$ , and  $X_{18}^T$  were added. For each clause solution, a clause module was created in a 4.5-cm-long glass tube with outer diameter of 0.5 cm and inner diameter of 0.3 cm. A base layer of 5% polyacrylamide gel was polymerized in the bottom 3.2 cm of the tube. A probe layer of 5% polyacrylamide gel containing the clause solution was polymerized on top of the base layer. A library module was prepared as above, but instead of a clause solution, 500 pmol of the full library in 100  $\mu$ l was used (28). The end of the module destined for the hot chamber was plugged with 5% polyacrylamide gel containing bromophenol blue and xylene cyanol dyes. The hot chamber was brought to 65°C and the cold chamber to 15°C. Electrophoresis was performed at 12 V/cm. Movement of the dyes through the gel provided a means of monitoring progress and of detecting possible leaks at the interface between the modules. Electrophoresis was stopped when the Xylene Cyanol dye had gone through the modules and into the cold buffer, approximately 4 hours.

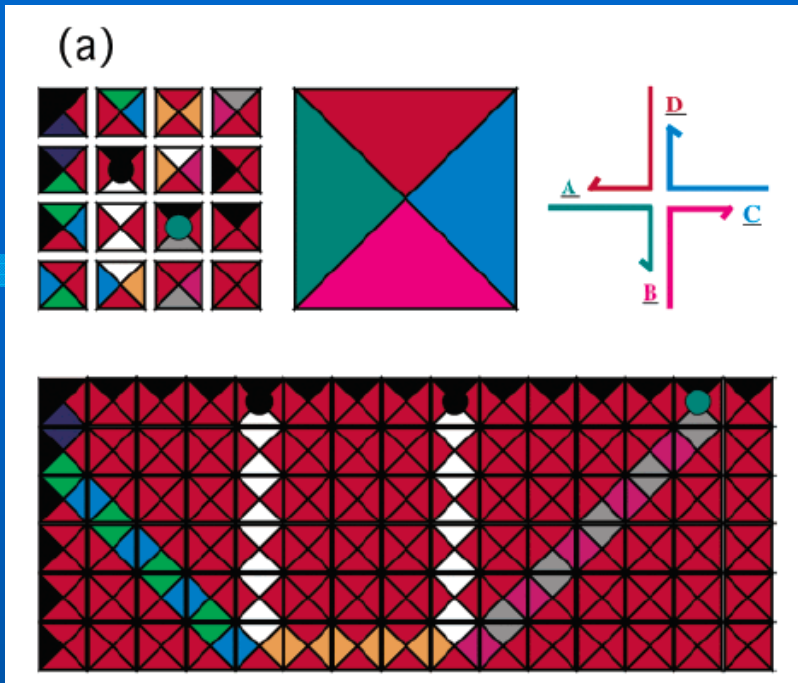

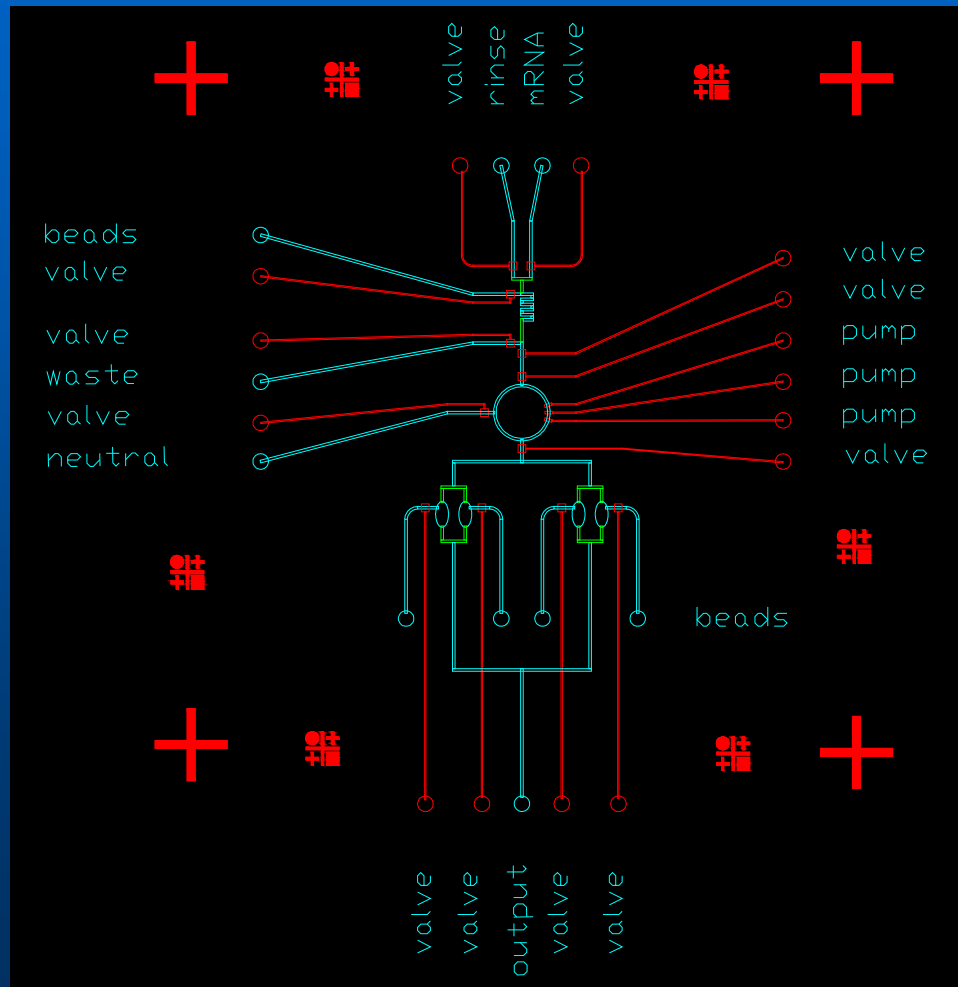

FIGURE 7: Wang tiles and algorithmic assembly. (a) Wang tiles. The upper left shows 16 wang tiles that fit together in the mosaic below according to the rule that each edge is flanked by the same color (modified from ref 40). The relationship between Wang tiles and a branched junction with a variety of sticky ends is illustrated at the upper center and right. (b) A four-bit XOR self-assembly. At the top of the panel is a TX tiles with its reporter strand emphasized in red. Below this are schematics of the input tiles (blue), initiator tiles (green), and gating tiles (red). The four possible inputs to the XOR gate correspond to sticky ends on the bottom domains of the red tiles. The schematic tiles are shown to self-assemble to produce the output arrangement of red tiles in the schematic below this. At the bottom, the answer is extracted by ligation of the reporter strands, which are later subjected to partial restriction.
